It is essential that winter sports pitches are frequently aerated/decompacted to keep the grass sward in the healthiest condition possible.

Aeration /decompaction will allow oxygen into the soil profile and carbon dioxide out, this is known as gaseous exchange. This promotes a healthy root structure to support the plant. This also stimulates the microbial activity in the soil that helps to produce the nutrient and breaks down the organic matter in the soil to maintain a good soil structure.

Aeration /decompaction also aids drainage through the soil by keeping an open structure to the soil. It must be stressed that it is not a drainage system.

Overseeding should take place on worn areas every year to maintain a surface that is suitable for winter sports.

This is the minimum of maintenance that should be carried out to winter sports pitches.
